MediLens AI - Report Summary

Educational information about laboratory results - not a diagnosis.

Source file: sample_cbc.pdf
Report type: Complete Blood Count (CBC)
Report date: 2026-08-12
Generated: 2026-09-26 15:00 UTC | Language: en

This tool provides general educational information about laboratory results and is not a medical diagnosis or a substitute for professional medical advice. Laboratory results should be interpreted in the context of a person's symptoms, history, examination, and the reference ranges provided by the laboratory. Consult a qualified healthcare professional for personalized interpretation.

1. Summary

This report contains 9 measurements. 5 are within the reference range shown on the report, 4 are below it, 0 are above it, and 0 could not be classified because no usable reference range was found. Values outside the range shown on your report: Hemoglobin, RBC Count, Hematocrit, MCH. This is an educational explanation, not a diagnosis. Please discuss these results with a qualified healthcare professional.

2. Reported values

Test	Result	Unit	Reference range	Status
Hemoglobin	10.8	g/dL	13.0 - 17.0	Below range
RBC Count	4.1	mill/cumm	4.50 - 5.50	Below range
WBC Count	8400	cells/cumm	4,000 - 11,000	Within range
Platelet Count	250000	cells/cumm	150,000 - 450,000	Within range
Hematocrit	33.5	%	40.0 - 50.0	Below range
MCV	81.7	fL	80.0 - 100.0	Within range
MCH	26.3	pg	27.0 - 32.0	Below range
MCHC	32.2	g/dL	32.0 - 36.0	Within range
RDW	14.1	%	11.5 - 14.5	Within range

3. Values outside the report's reference range

Hemoglobin: 10.8 g/dL g/dL (reported range 13 - 17) - below the printed range

nly ordered during routine health check-ups, before or after surgery, and when a person has symptoms such as unusual tiredness or shortness of breath. Doctors interpret a hemoglobin result together with other measurements (red blood cell count, hematocrit, MCV) and with the person's symptoms and history, because a single measurement has many possible explanations. The value reported on your report is below the reference range printed by the laboratory. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

RBC Count: 4.1 mill/cumm mill/cumm (reported range 4.5 - 5.5) - below the printed range

The RBC count measures how many red blood cells are present in a volume of blood. The value reported on your report is below the reference range printed by the laboratory. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

Hematocrit: 33.5 % % (reported range 40 - 50) - below the printed range

Hematocrit is the share of blood volume occupied by red blood cells. The value reported on your report is below the reference range printed by the laboratory. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

MCH: 26.3 pg pg (reported range 27 - 32) - below the printed range

MCH describes the average amount of hemoglobin inside a red blood cell. The value reported on your report is below the reference range printed by the laboratory. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

4. Educational context

Hemoglobin: Hemoglobin: nly ordered during routine health check-ups, before or after surgery, and when a person has symptoms such as unusual tiredness or shortness of breath. Doctors interpret a hemoglobin result together with other measurements (red blood cell count, hematocrit, MCV) and with the person's symptoms and history, because a single measurement has many possible explanations.

RBC Count: The RBC count measures how many red blood cells are present in a volume of blood. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

Hematocrit: Hematocrit is the share of blood volume occupied by red blood cells. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

MCH: MCH describes the average amount of hemoglobin inside a red blood cell. Many factors ? including the testing method used, how the sample was collected, and normal biological variation ? can influence a single laboratory result.

5. Questions you may want to discuss with a healthcare professional

- Ask your healthcare professional what your Hemoglobin result means in the context of your symptoms, history and examination.
- Ask your healthcare professional what your RBC Count result means in the context of your symptoms, history and examination.
- Ask your healthcare professional what your Hematocrit result means in the context of your symptoms, history and examination.
- Ask your healthcare professional what your MCH result means in the context of your symptoms, history and examination.

6. Limitations

- A single laboratory result on its own cannot confirm or exclude any medical condition.
- Reference ranges are specific to the laboratory and method that produced them; the range printed on your report takes precedence.
- Laboratory results should always be interpreted together with your symptoms, medical history and examination.
- This explanation was generated for educational purposes from the values on your report and general health information.
- It is not a diagnosis, and it does not replace advice from a qualified healthcare professional.
- Values flagged here reflect the numbers on your report; if a value looks different from your original copy, please re-check it.
